

Wrong probabilities

- What is different in this text?

3. 2

© Klein S. T. and Wiseman Y.

Static Huffman

- A known tree is used for compressing a file.
 - A different tree can be used for each type of file. For example a different tree for an English text and a different tree for a Hebrew text.
- Two passes on file. One pass for building the tree and one for compression.

3. 1

© Klein S. T. and Wiseman Y.

Canonical Huffman Trees

3. 4

© Klein S. T. and Wiseman Y.

Adaptive Huffman

- x_t is encoded with tree of x_1, \dots, x_{t-1} .
- Tree is changed during compression.
- Only one pass.
- No need to transmit the tree.
 - Two possibilities:
 - At the beginning assume each item appeared once.
 - At the beginning probabilities are wrong but after a large amount of data the error is negligible.
 - When a new character appears send an escape character before it.

3. 3

© Klein S. T. and Wiseman Y.

Example of a canonical tree

- Suppose the lengths are:
 - A-3, B-2, C-4, D-2, E-3, F-3, G-4
- The sorted list is:
 - B-2, D-2, A-3, E-3, F-3, C-4, G-4

Item	L_i	2^{-L_i}	$\sum_{j=1}^{i-1} 2^{-L_j}$
B	2	0.01	0.0000
D	2	0.01	0.0100
A	3	0.001	0.1000
E	3	0.001	0.1010
F	3	0.001	0.1100
C	4	0.0001	0.1110
G	4	0.0001	0.1111

3. 6

© Klein S. T. and Wiseman Y.

Algorithm for canonical trees

- Find a Huffman tree with lengths L_1, \dots, L_n for the items.
- Sort the items according to their lengths.
- Assign to each item the first L_i bits after the binary point of $\sum_{j=1}^{i-1} 2^{-L_j}$

Errors in Huffman coded files

• In the beginning God created the heaven and the earth. And the earth was without form, and void; and darkness was upon the face of the deep. And the Spirit of God moved upon the face of the waters. And God said, Let there be light: and there was light. And God saw the light, that it was good: and God divided the light from the darkness. And God called the light Day, and the darkness he called Night. And the evening and the morning were the first day. And God said, Let there be a firmament in the midst of the waters, and let it divide the waters from the waters...

• What will happen if the compressed file is read from arbitrary points?

- : **ac** darkness was upon the face
- **cs**oaraters. And God said, Let there be light
- **d** lnrthat it was good: and God divided
- **.a**uya dy, and the darkness he called Night
- **c** y. And God said, Let there be a firmament in the midst

Why canonical trees?

- A canonical tree can be transferred easily.
 - ▶ Send number of items for every length.
 - ▶ Send order of items.
- Canonical codes synchronize faster after errors.
- Canonical codes can be decoded faster.

3. 7

© Klein S. T. and Wiseman Y.

Definitions

- Let P_1, \dots, P_n be the probabilities of the items (The leaves of the Huffman tree).
- Let L_1, \dots, L_n be the length of codewords.
- Let X be the set of internal nodes in the Huffman tree.
- $\forall x \in X$ let I_x be the set of leaves in the sub-tree rooted by x .

3. 10

© Klein S. T. and Wiseman Y.

Synchronization after error

- If the code is not an affix code:

3. 9

© Klein S. T. and Wiseman Y.

Synchronization's probability

- Let S denote the event that the synchronization point is at the end of the codeword including $x \in X$.

$$P(S) = \sum_{x \in X} \frac{\sum_{y \in I_x} P_y Q(x, y)}{\sum_{y \in I_x} P_y} \cdot P(x) = \frac{\sum_{x \in X} \sum_{y \in I_x} P_y Q(x, y)}{W}$$

3. 12

© Klein S. T. and Wiseman Y.

Formulas

- Average codeword's length is $w = \sum_{i=1}^n P_i L_i$
- The Probability that an arbitrary point in the file will be in node x is: $P(x) = \frac{\sum_{y \in I_x} P_y}{W}$
- $\forall x \in X$ and $\forall y \in I_x$ define:
- $Q(x, y) = \begin{cases} 1 & \text{if the path from } x \text{ to } y \text{ corresponds to a} \\ & \text{sequence of one or more codewords in the code} \\ 0 & \text{otherwise} \end{cases}$

3. 11

© Klein S. T. and Wiseman Y.

Synchronization

- canonical trees synchronize better since every sub-tree of a canonical tree is a canonical tree itself.
- Expected number of bits until synchronization is:

$$E = \frac{W}{P(S)}$$

3. 14

© Klein S. T. and Wiseman Y.

Probability for a canonical tree

- Nelson's trees are the trees described in 2.2 with some other features.

3. 13

© Klein S. T. and Wiseman Y.

Skeleton Trees

- No need to save the whole tree e.g. if a codeword starts with 1101, it ought to be of length 9 bits. Thus, we can read the following 5 bits as a block.

```

0 000
1 0010
2 0011
3 0100
4 01010
5 01011
6 01100
7 01101
8 011100
9 011101
10 011110
11 011111
12 100000
13 100001
14 100010
15 100011
16 1001000
17 1001001
18 1001010
19 ...
20 ...
21 ...
22 ...
23 ...
24 ...
25 ...
26 ...
27 ...
28 ...
29 1010101
30 1010110
31 10101110
32 10101111
...
62 11001101
63 110011100
64 110011101
...
125 111011010
126 1110110110
127 1110110111
...
199 1111111111
    
```

3. 16

© Klein S. T. and Wiseman Y.

Expected synchronization

3. 15

© Klein S. T. and Wiseman Y.

Definition

- Let $m = \min\{ l \mid n_l > 0 \}$ where n_l is the number of codewords of length l .
- Let $base(l)$ be:
 - $base(m) = 0$
 - $base(l) = 2(base(l-1) + n_{l-1})$
- Let $seq(l)$ be:
 - $seq(m) = 0$
 - $seq(l) = seq(l-1) + n_{l-1}$

3. 18

© Klein S. T. and Wiseman Y.

Illustration of a Skeleton Tree

- This is the skeleton tree for the code on the previous slide. It has 49 nodes, while the original one has 399 nodes.

3. 17

© Klein S. T. and Wiseman Y.

An example for values

- These are the values for the code depicted on the previous slides.

l	n_l	$\text{base}(l)$	$\text{seq}(l)$	$\text{diff}(l)$
3	1	0	0	0
4	3	2	1	1
5	4	10	4	6
6	8	28	8	20
7	15	72	16	56
8	32	174	31	143
9	63	412	63	349
10	74	950	126	824

3. 20

© Klein S. T. and Wiseman Y.

Definition (cont.)

- Let $B_s(k)$ denote the s -bit binary representation of the integer k with leading zeros if necessary.
- Let $I(w)$ be the integer value of the binary string w , i.e. if w is of length of l , $w = B_l(I(w))$.
- $I(w) - \text{base}(l)$ is the relative index of codeword w within the block of codewords of length l .
- $\text{seq}(l) + I(w) - \text{base}(l)$ is the relative index of w within the full list of codewords. This can be rewritten as $I(w) - \text{diff}(l)$, for $\text{diff}(l) = \text{base}(l) - \text{seq}(l)$.
- Thus all one needs is the list of $\text{diff}(l)$.

3. 19

© Klein S. T. and Wiseman Y.

Reduced Skeleton Trees

- Define for each node v of the Skeleton Tree:

- If v is a leaf
 - $\text{lower}(v) = \text{upper}(v) = \text{value}(v)$
- If v is an internal node
 - $\text{lower}(v) = \text{lower}(\text{left}(v))$
 - $\text{upper}(v) = \text{upper}(\text{right}(v))$

- Reduced Skeleton Tree is the smallest subtree of the original Skeleton Tree for which all the leaves w hold:

- $\text{upper}(w) \leq \text{lower}(w) + 1$

3. 22

© Klein S. T. and Wiseman Y.

Decoding Algorithm

- ```

tree_pointer ← root
i ← 1
start ← 1
while i < length_of_string
 if string[i] = 0 tree_pointer ← left(tree_pointer)
 else tree_pointer ← right(tree_pointer)
 if value(tree_pointer) > 0
 codeword ← string[start... (start + value(tree_pointer) - 1)]
 output ← table[| (codeword) - diff[value(tree_pointer)] |]
 start ← start + value(tree_pointer)
 i ← start
 tree_pointer ← root
 else i ++

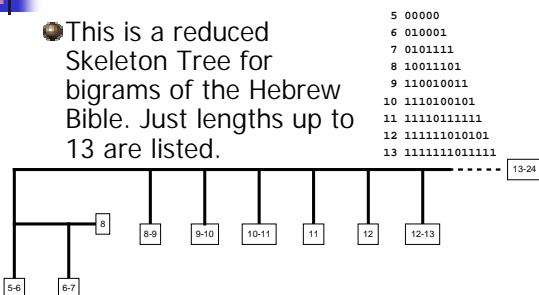

```

3. 21

© Klein S. T. and Wiseman Y.

## Another example of a reduced tree

- This is a reduced Skeleton Tree for bigrams of the Hebrew Bible. Just lengths up to 13 are listed.

3. 24

© Klein S. T. and Wiseman Y.

## Illustration of a reduced tree

- This is the reduced tree of the previous depicted tree.
- If 111 have been read we can know that the length of the codeword is either 9 or 10.
- If the bits after 111 were 0110, we would have performed four more comparisons and still cannot know if the length is 9 or 10

3. 23

© Klein S. T. and Wiseman Y.

## Affix codes

- Affix codes are never synchronizing, but they can be decoded backward.
- PL/1 allows files on magnetic tapes to be accessed in reverse order.
- Information Retrieval systems use concordance points to the words' locations in the text. When a word is retrieved, typically, a context of some words is displayed.

3. 26

© Klein S. T. and Wiseman Y.

## Algorithm of reduced trees

```

tree_pointer ← root
i ← start - 1
while i < length_of_string
 if string[i] = 0 tree_pointer ← left(tree_pointer)
 else tree_pointer ← right(tree_pointer)
 if value(tree_pointer) > 0
 len ← value(tree_pointer)
 codeword ← string[start...(start+len-1)]
 if flag(tree_pointer) = 1 and 2-I(codeword) ≥ base(len+1)
 codeword ← string[start...(start+len)
 len ++
 output ← table[I(codeword)-diff[len]]
 tree_pointer ← root
 i ← start ← start + len
 else i ++

```

3. 25

© Klein S. T. and Wiseman Y.

## Markov chains

- A sequence of events, each of which depends only on  $n$  events before it, is called an  $n^{\text{th}}$  Order Markov chain.
- First order Markov chain - Event  $t$  is depending just on event  $t-1$ .
- $0^{\text{th}}$  order Markov chain - events are independent.
- Examples:
  - ▶ Fibonacci sequence is a second order chain.
  - ▶ An arithmetic sequence is a first order chain.

3. 28

© Klein S. T. and Wiseman Y.

## Non-Trivial Affix codes

- Fixed length codes are called trivial affix codes.
- Theorem: There are infinite non-trivial complete affix codes.
- Proof: One non-trivial code is showed in this slide. Let  $A = \{a_1, \dots, a_n\}$  be an affix code. Consider the set  $B = \{b_1, \dots, b_{2n}\}$  defined by  $b_{2i} = a_i 0$ ,  $b_{2i-1} = a_i 1$  for  $1 \leq i \leq n$ . Obviously B is an affix code.

3. 27

© Klein S. T. and Wiseman Y.

## Clustering

- Markov chains for Huffman trees can be expanded for  $n^{\text{th}}$  order chains.
- Overhead for saving so many trees can be very high.
- Similar trees can be clustered into a one tree, which will be the average of the original trees.
  - ▶ Example: The trees of  $v$  and  $b$  may be similar since they have a similar sound.

3. 30

© Klein S. T. and Wiseman Y.

## Markov chain of Huffman trees

- A different Huffman tree for each item in the set.
- The tree for an item  $x$  will have the probabilities of each item to appear after  $x$ .
- Examples:
  - ▶  $u$  will have a much shorter codeword in  $q$ 's tree, than other trees.
  - ▶  $v$  will have a much longer codeword after  $x$ .
- This method implements a first order Markov chain.
