- Let $x_1,\ldots,x_n$ be a sequence of items.
- We want to find a sub-sequence $x_k,\ldots,x_m$ which holds: $P(x_k,\ldots,x_m) > \prod_{i=k}^{m} P(x_i)$
- For example $p(qu) > p(q) \cdot p(u)$.
- Huffman and Arithmetic don't look on the item's environment.

LZ77

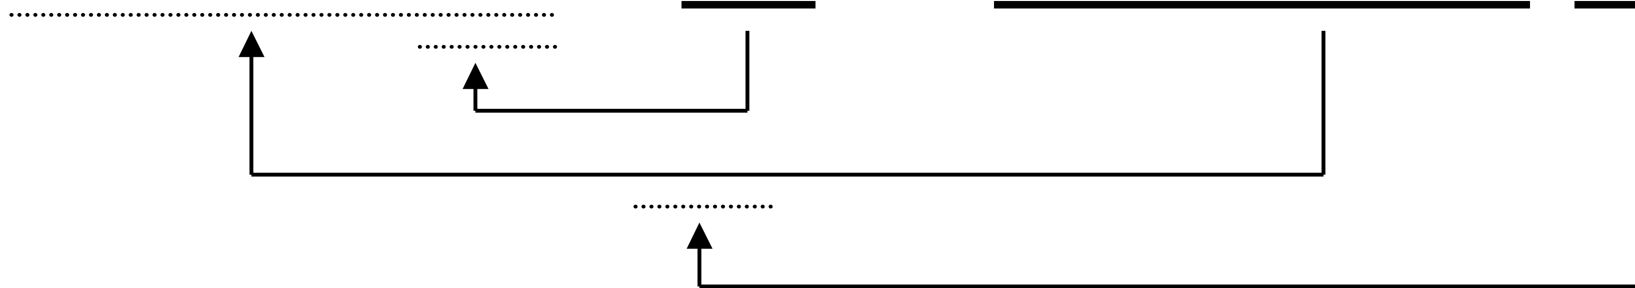
An outcry in Spain is an outcry in vain



An outcry in Spa(6,3)is a(22,12)v(21,3)

aaaaaaaaaa

a(1,9)

© Klein S. T. and Wiseman Y.

Implementation of LZ77

- Pointers should be distinguished from other items.
-

- A null pointer is (0,0).
- If two pointers are adjacent, the first character of the second string will be encoded separately.
- Offset is accommodated in n bits so the maximum offset is 2^n

© Klein S. T. and Wiseman Y.

Some versions of LZ77

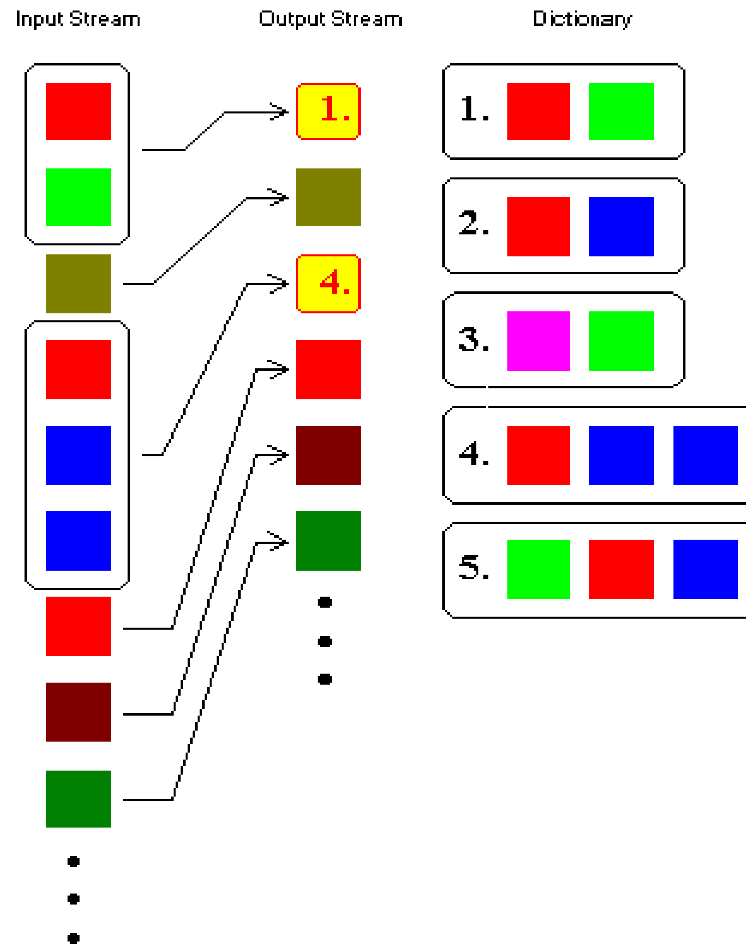
- LZSS - A flag bit for distinguishing pointers from the other items.
- LZR - No limit on the pointer size.
  - Example: $1234_{10}=10011010010_2$

    100101100011010010

    $\underbrace{100}_{3}\underbrace{1011}_{4}\underbrace{00011010010}_{11}$
- LZH - Compress the pointers in Huffman coding.

© Klein S. T. and Wiseman Y.

LZ78



© Klein S. T. and Wiseman Y.

LZW

- A version of LZ78.
- If $x \in$dictionary then all prefix$(x) \in$dictionary
- Finds the longest string in dictionary. If $x_1,\ldots,x_n$ in dictionary but $x_1,\ldots,x_{n+1}$ not in dictionary, add $x_1,\ldots,x_{n+1}$ to dictionary.

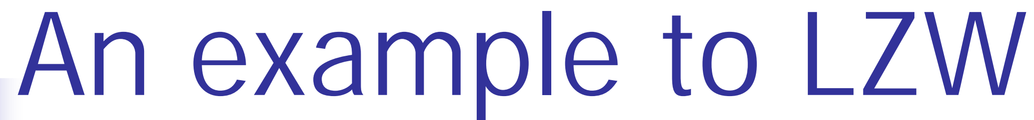
© Klein S. T. and Wiseman Y.

LZW algorithm

- dictionary ← single characters
- w ← first character of input

step:
- k ← next character
- if EOF then output(code(w)); exit
- else
  - if wk ∈ dictionary then w ← wk
  - else
    - Output (code(w))
    - dictionary ← wk
    - w ← k
  - goto step

© Klein S. T. and Wiseman Y.



An example to LZW

- T=ababcbababaaaaaaa

w	a	b	a	ab	c	b	ba	b	ba	bab	a	a	aa	a	aa	aaa	a
wk	ab	ba	ab	abc	cb	ba	bab	ba	bab	baba	aa	aa	aaa	aa	aaa	aaaa	
out	1	2		4	3		5			8	1		10			11	1
dict'	ab	ba		abc	cb		bab			baba	aa		aaa			aaaa	

- Dictionary:

code	1	2	3	4	5	6	7	8	9	10	11	12
string	a	b	c	ab	ba	abc	cb	bab	baba	aa	aaa	aaaa

© Klein S. T. and Wiseman Y.

Dictionary considerations

- Dictionary size is determined according to pointer's length. Pointer's length can be changed during processing.
- When dictionary is full, one of these can be done:
  - Delete the whole dictionary.
  - Delete strings according to LRU.
  - Each string has a counter. A string whose counter is the lowest will be deleted.
  - Stop to update the dictionary.
  - Double the dictionary's size.

© Klein S. T. and Wiseman Y.

LZW decoding

code	1	2	4	3	5	8	1	10	11	1
decoded text	a	b	ab	c	ba	bab	a	aa	aaa	a
dictionary		ab	ba	abc	cb	bab	baba	aa	aaa	aaaa

- In these stages the decoder gets a code which isn't in the dictionary yet.
- In such cases, the last code's string concatenated with first item in the string, will be the new string.

© Klein S. T. and Wiseman Y.

Some features of LZW

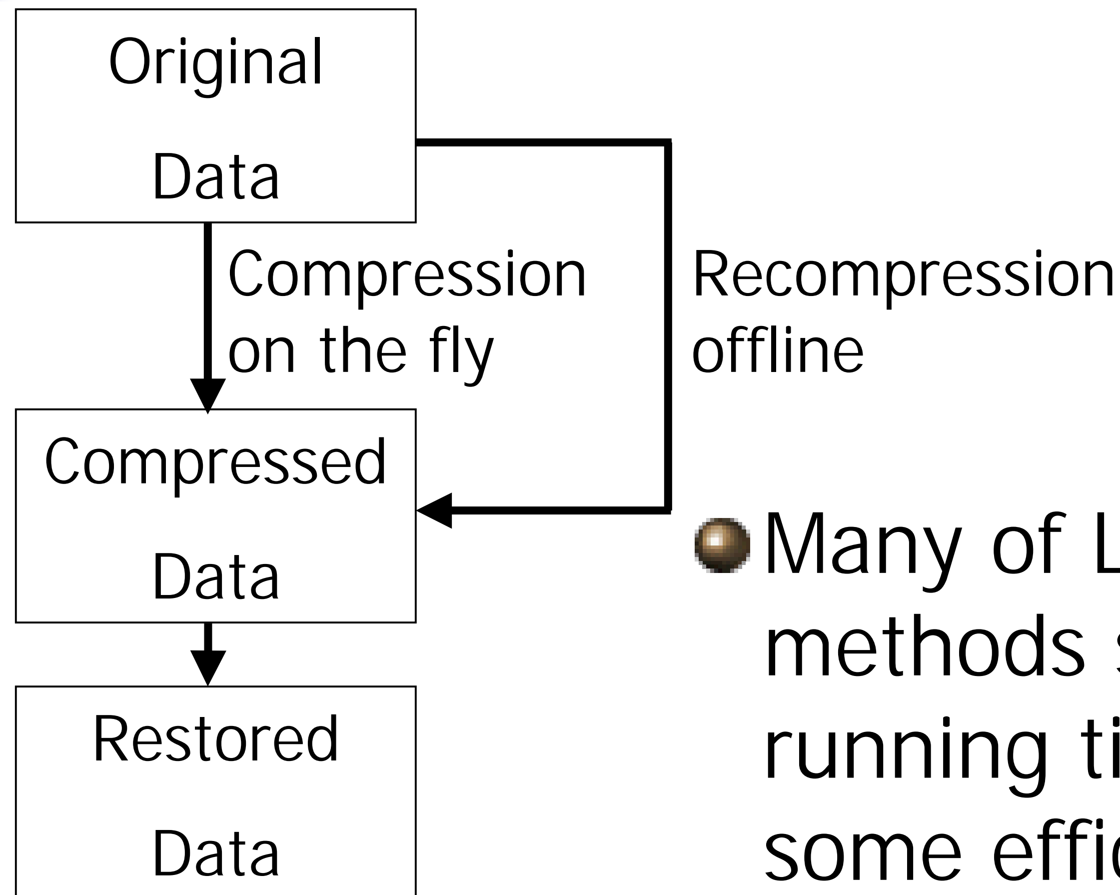
- In order to reduce dictionary size:

code	1	2	3	4	5	6	7	8	9	10	11	12
string	a	b	c	1b	2a	4c	3b	5b	8a	1a	10a	11a

- If there is a long string like "Jerusalem", all its sub-strings will be in the dictionary too.
  - J, Je, Jer, Jeru, Jerus, Jerusa, Jerusal, Jerusale, Jerusalem.
  - LZMW - concatenate last two strings instead of string and a single item.
  - Strings like aa...a will have in LZMW, $O(\log(n))$ entries in the dictionary instead of $O(\sqrt{n})$ in LZW.

© Klein S. T. and Wiseman Y.

Recompression



- Many of Lempel-Ziv methods save some running time by losing some efficiency.

 © Klein S. T. and Wiseman Y.

Optimal partition

- D = { abc, ab, cdef, d, de, ef, f }
- T = abcdef
- Greedy method will yield abc-de-f.
- A better partition would be ab-cdef.
- If the words in D are encoded by 1, 2, 3, 4, 5, 6 and 6 bits respectively, abc-d-ef is the optimal partition.

© Klein S. T. and Wiseman Y.

Definitions

- Let $S=S_1S_2\ldots S_n$ be a string. Each S_i belongs to an alphabet Σ.
- Let D be a dictionary contains words from Σ.
- An increasing sequence of indices $i_0=0,\ i_1,\ i_2,\ldots$ Should be found s.t.: $S=S_1S_2\ldots S_n=S_1\ldots S_{i_1}S_{i_1+1}\ldots S_{i_2}\ldots$ with $S_{i_j+1}\ldots S_{i_{j+1}}\in D$ for $j=0,1,\ldots$

© Klein S. T. and Wiseman Y.

Encoding

- f:D→{0,1}* assigns to each element of the dictionary a binary string.
- f produces a code which is uniquely decipherable.
- A fixed length code can be good, if the occurrences of the elements of D in S is nearly uniform.
- We look for the minimal $\sum_{j\geq 0} \left| f(S_{i_j+1} \ldots S_{i_{j+1}}) \right|$

© Klein S. T. and Wiseman Y.

Reduction to The Shortest Path

- Vertex i corresponds to the character S_i for $i \le n$ and $n+1$ corresponds to the end of the text.
- An ordered pair (i,j) with $i<j$ belongs to E if and only if $S_i \ldots S_{j-1} \in D$.
- The label L_{ij} is defined for edge $(i,j) \in E$ as $\left| f(S_i \ldots S_{j-1}) \right|$
- Dijkstra's worst case complexity for finding the shortest path is the highest between $O(|V|^2)$ and $O(|E|+|V|\log|V|)$.
- In this case the graph contains no cycle, since all of the edges are of the form (i,j) with $i<j$, so the complexity is $O(|E|)$.

© Klein S. T. and Wiseman Y.

Improving the graph

- Before adding edge (i,j) to E, check if it is possible to reach vertex j directly from every vertex in $\{k | (k,i) \in E\}$, without passing through vertex i.
- If so, we assume the triangle inequality which holds for many practical schemes. Hence edge (i,j) can be pruned.
- If after having checked all the edges emanating from vertex i, none of have been adjoined to E, vertex i and all the incoming edges on vertex i can be pruned.

© Klein S. T. and Wiseman Y.

Pruning

- $L_{kj} \leq L_{ki} + L_{ij}$ for $k < i < j$

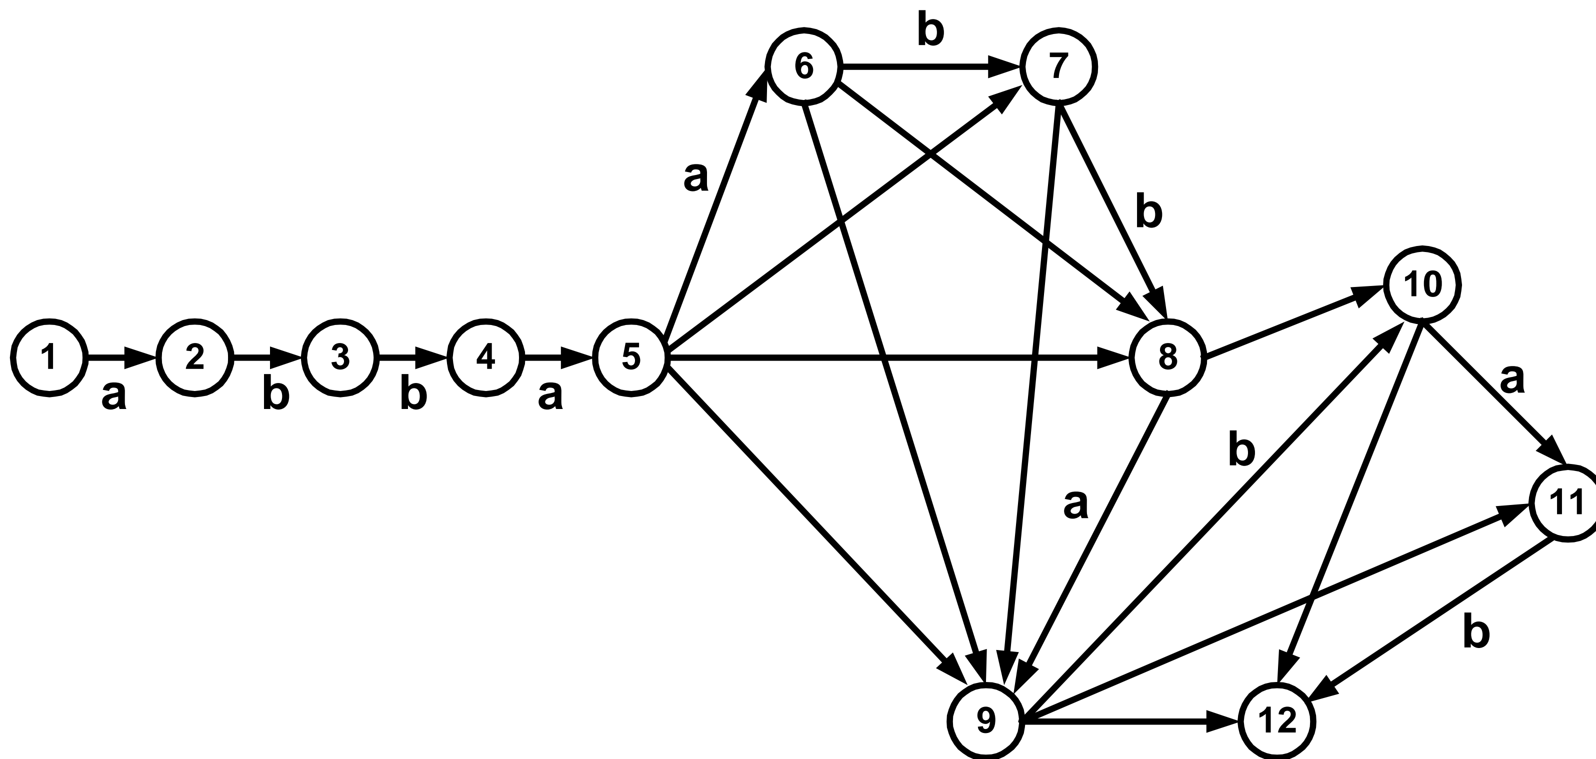
 © Klein S. T. and Wiseman Y.

The pruning algorithm

- $E \leftarrow \emptyset$; $V \leftarrow \{1,\ldots,n,n+1\}$
- for $i \leftarrow 1$ to n
  - $Pred(i) \leftarrow \{k \mid (k,i) \in E\}$
  - $Succ_Candidates(i) \leftarrow \{j \mid S_i \ldots S_{j-1} \in D\}$
  - add_edge ←FALSE
  - for all $j \in Succ_Candidates(i)$
    - all_connected←TRUE
    - for all $k \in Pred(i)$
      - if $(k,j) \notin E$ then all_connected←FALSE
    - if not all_connected then
      - $E \leftarrow E \cup \{(i,j)\}$
      - Added_edge ←TRUE
  - if not added_edge then
    - $V \leftarrow V \setminus \{i\}$
    - $E \leftarrow E \setminus \{(j,i) \mid j \in Pred(i)\}$

Example

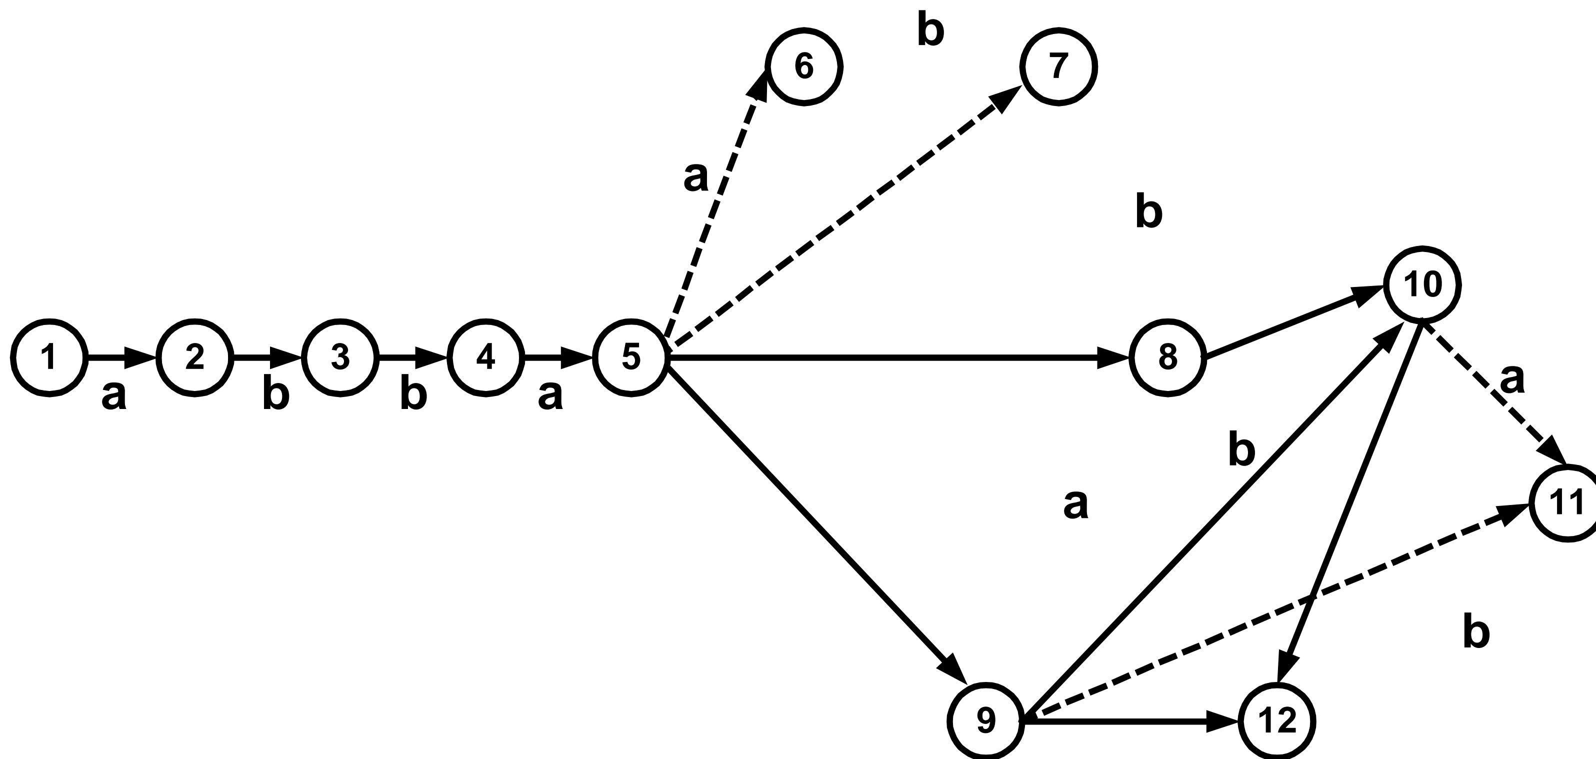
- A graph for the string abbaabbabab



© Klein S. T. and Wiseman Y.

Example (cont.)

- The graph after pruning



© Klein S. T. and Wiseman Y.

Shortest Path Algorithm

- $SPL(1) \leftarrow 0$
- for $i \leftarrow 2$ to $n+1$
  - if $i \in V$ then
    - $SPL(i) \leftarrow \infty$
    - for all $j \in Pred(i)$
      - $t \leftarrow SPL(j) + L_{ji}$
      - if $SPL(i) > t$ then
        - $SPL(i) \leftarrow t$
- Each edge (j,i) is referenced exactly once, so the time complexity is $O(|E|)$.
